

2.

a) A demand planner is someone responsible for predicting future product requirements, meaning how many products will be sold, based on customer demand. This helps companies to optimize working capital by reducing extra stockpiling while avoiding stockouts.

b) The product forecasts help the demand planner to accurately estimate product demand while maintaining improved inventory and satisfied customers.

c) The frequency changes from company to company, but typically they use either weekly or monthly depending on the company's cycle.

d) The main data needed to get started would be the historical demand data, where you can observe the past sales, including their price changes over time. This data could show you how much the product was sold at a certain time and would eventually help the demand planner to make more efficient models.

e) To the demand planners, I would ask how often they update their forecast models; for example, do you change it due to a new product or a price change? I would also like to know what the current forecasting problems are and how you overcome them.

f) To show the demand planners that the results should be trusted, I would demonstrate an example model using historical data. I compare the predicted demand from my model with the actual demand. Using this comparison, we could show that the model accurately predicts past demand, so it can also work well in future models.

g) To productionize the model, the data needs to be clean, consistent, and structured. It needs to be clean, organized, and easy to interpret, so no mistakes will be made when the data is reused.

h) My best guess would be a dashboard for the models with all the important values highlighted. This way, they could access the information with ease while not bothering to look at 50 other things they do not recognize. It would be clean and an efficient way

j) For a, b, and d, NetSuite and IBF were used to answer the question. For c and g, Oracle was used to answer the question. Other questions were my guess.
